

Summary of Carcinogenic Potency Database by Target Organ

A chemical is listed under each organ evaluated as positive in an experiment in that species by at least one author. For NCI/NTP an evaluation of “clear” or “some” evidence of carcinogenicity is considered positive. A chemical may be listed under several target organs and every chemical listed in the table is positive in at least one species. In order to compare results in rats and mice, symbols follow chemicals tested in both species: a [†] indicates that the chemical is positive at some site in both species, and a [‡] indicates that it was tested in both rats and mice but positive in only one.^a

Example: Adrenal gland is the first of 35 target sites in the table. Under adrenal gland, one chemical is listed in hamsters, 8 in mice, and 18 in rats. If a chemical name is followed by a superscript (either [†] or [‡]), this indicates that the CPDB includes test results in both rats and mice, e.g., under adrenal gland in rats 2-mercaptopbenzothiazole but not isomazole, has a superscript. Since isomazole has no superscript, it only has tests in the CPDB in the species reported, in this case rats. The superscript [†] for 2-mercaptopbenzothiazole, indicates that the chemical has been tested in both rats and mice but induced tumors only in the reported species, in this case rats. The superscript [‡]; for 1,2-dibromo-3-chloropropane (DBCP) indicates that DBCP is carcinogenic at some target site in both rats and mice. Although the superscript [‡]; does not indicate whether DBCP induced tumors at the same target site in both rats and mice, this can easily be determined by looking at mice under adrenal gland for the chemical name DBCP. Since it is not there, DBCP induced tumors in mice only at sites other than the adrenal gland. In contrast, pentachloroanisole[†]; induced adrenal tumors in both species, since it is listed under that site for both species. By comparing the chemicals with superscripts listed under each species, the reader can determine that pentachloroanisole is the only chemical that induced adrenal tumors in both rats and mice. The superscripts [†] and [‡]; apply only to results in rats and mice: for example, hamsters are reported under adrenal gland for urethane with the symbol [‡]; indicating that urethane was positive at some site in rats and mice; however, the superscript does not indicate anything about hamsters.

N = the number of chemicals with at least one positive test at that site in that species. Since many chemicals induce tumors at more than one site in a given species, many chemicals appear more than once in the table. The total number of positive chemicals in the CPDB for each species is 562 for rats, 442 for mice, 44 for hamsters, 11 for monkeys, 3 for dogs and 1 each for bush babies and tree shrews.

^a There was no reported target site in one species (rats or mice) for 4 chemicals with superscripts, but the chemical was evaluated by the published author as a carcinogen: Aldrin[‡], Dieldrin[‡], N-Nitrosopyrrolidine[‡]; and Urethane[‡].

^b Nasal cavity includes tissues of the nose, nasal turbinates, paranasal sinuses and trachea.

^c Oral cavity includes tissues of the mouth, oropharynx, pharynx, and larynx.

In this table, NCI evaluations of “associated” are not considered positive. For a few cases, however, an NCI Technical Report indicated that tumors were “associated” with compound administration, and the NTP later assigned a “positive” evaluation, while noting that “these experiments were particularly difficult to evaluate based on the wording in the Technical Report Summaries” (Haseman *et al.*, *Environ. Health Perspect.* 74: 229-235, 1987). These sites are not listed in the compendium: 2-Amino-5-nitrothiazole (hematopoietic
